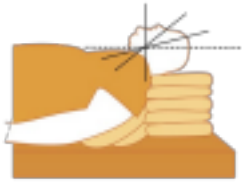
# WHY IS RAMPING IMPORTANT?

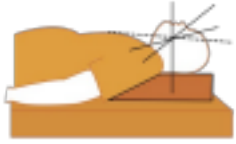
## RAMPING OF PATIENTS

Ramping of patients has been shown to improve visualisation of the vocal cords during direct laryngoscopy and to improve first pass intubation success. This is especially important for higher BMI patients. Ramping involves elevation of the head and shoulders to achieve alignment of the sternal notch and the external auditory meatus.

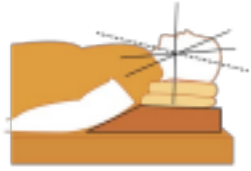


Ramping is typically achieved using pillows or linen to position the patient in the “sniffing the morning air” position. This may be challenging when adequate linen or pillows are not readily available, or the patient is restless with potential ramp instability.

## OPTIRAMP



The OptiRamp was developed to provide a simple, stable ramping solution, adequate for most patients’ profits. The OptiRamp is positioned under the patients’ shoulders to elevate the head and neck so to achieve alignment of the sternal notch and external auditory meatus. If additional ramping is required, then a head ring or linen can



Position OptiRamp under head and neck of patient. The OptiRamp is covered in a robust material with water resistant seams that can be easily disinfected between patients using the same materials and methods used to clean the theatre table itself. Bleaches, alcohol, and chlorhexidine-based disinfectants are all suitable for cleaning.

The foam density is optimised to provide the required level of stability but can also be comfortable enough for the patient. Durability and longevity have guided all materials used.

## ADVANTAGES

# OF OPTIRAMP

Simply wiped down between patients.

Easy to move around and store.

Less likely to move or become dislodged if patient is restless or head requires manipulation during intubation.

More patients likely to be ramped

Long expected lifetime of foam and covering. meaning lower risk intubations.

Single unit that can quickly be inserted making it suitable for emergency rooms as well as theatre.

Patients report improved comfort with the OptiRamp compared to lying flat on the theatre table.

OptiRamp suits most patients but can be raised using standard pillows or linen if additional ramping is required. (Future ramp expanders are being designed to allow even greater flexibility).

Manual ventilation with a manual resuscitator is easier with the OptiRamp than unstable cushions or linen and OptiRamp can be quickly removed as a single unit should CPR be necessary.
